Brushless motors typically have a commutator and a set of commutator-side conductive segments. The commutator-side segments are commonly known in the art as commutator bars. Typically, the brushless motor can be operated on DC power, a pulsed DC power (PWM), or AC power. The segments have to be correctly phased so that the commutator-side segments and the brush-side can conduct current to and from the motor windings without damaging the windings and the commutator. A phased arrangement of commutator-side segments is typically created by connecting the commutator-side segments to the commutator and interconnecting them in a predetermined order. One embodiment of a motor having a brushless motor drive is disclosed in U.S. Pat. No. 5,886,249. The motor of this embodiment is mounted in a vehicle and is powered by a battery in the vehicle. The brushless motor drive has an input terminal electrically coupled to a battery that powers the brushless motor drive. A ground terminal is electrically connected to the vehicle frame. A first brushless motor segment carries current from the input terminal to the ground terminal. An output segment carries current from the ground terminal to the input terminal. Another embodiment of a brushless motor drive is disclosed in U.S. Pat. No. 5,999,883. This brushless motor drive has a brushless motor assembly disposed in a vehicle to rotate a wheel. The brushless motor assembly has an armature in a motor housing in which a plurality of phase windings are disposed. A number of rotor bars are disposed in the armature and are connected to one another. The rotor bars connect to a commutator and commutator segments. The commutator segments are connected to the phase windings. Yet another embodiment of a brush 3da54e8ca3
